1 **Abstract**

2  
3 In the present study influence of buckwheat flour and carboxymethylcellulose (CMC) on the  
4 production of sheetable gluten-free cookie dough of acceptable rheological properties and  
5 subsequently their effect on the quality of gluten-free cookies was studied. The buckwheat flour  
6 was used to replace 10, 20 and 30% of rice flour in gluten-free formulations. Cookie doughs of  
7 100% rice flour and 100% wheat flour served as control samples. The impact of CMC addition  
8 was examined on formulation containing 20% of buckwheat flour. Oscillatory and creep  
9 measurements were applied to test the effect of buckwheat flour and CMC on the viscoelasticity  
10 of gluten-free cookie dough. Frequency sweep results showed that all samples had solid elastic-  
11 like characteristics. Increase in the buckwheat flour addition led to decrease in storage modulus  
12 and zero shear viscosity and increase in  $\tan \delta$  and maximum creep compliance, while the  
13 addition of CMC led to increase in dough tenacity and resistance to deformation. Cookie dough  
14 containing 30% of buckwheat flour expressed the highest viscous properties, as revealed by  
15 relative viscous compliance value. The gluten-free dough containing CMC and buckwheat flour  
16 between 20 and 30% replacement level showed similar strength and extensibility as wheat  
17 cookie dough. The results of the physical and sensory evaluation of gluten-free cookies showed  
18 that buckwheat addition led to decrease in cookie hardness and fracturability and increase in  
19 eccentricity (deformation from regular shape) as well as the overall acceptability, as evaluated by  
20 untrained panellists.

21  
22 Key words: **gluten-free cookie, dough rheology, buckwheat, rice, carboxymethylcellulose**

# 1. Introduction

In recent years, there is a trend of utilizing pseudocereals (amaranth, quinoa, buckwheat) in gluten-free bakery formulations in order to improve the nutritional profile of final products. The reason for that is greater awareness among the scientists and technologists regarding unbalanced diet of celiac patients. According a recently published study there is an unbalance in the intake of carbohydrates, fat and protein in the gluten-free diet (Alvarez-Jubete et al., 2010). Moreover, most of the commercially available cereal based gluten-free products contain lower levels of B-vitamins, iron and fiber in comparison to their gluten-containing counterparts (Alvarez-Jubete et al., 2010).

One of the pseudocereals which could be used as functional gluten-free alternative is buckwheat since it has proved to be a good source of essential amino acids, dietary fiber, vitamin B, vitamin E, calcium, magnesium and iron (Alvarez-Jubete et al., 2010). Moreover, ethanolic extracts of buckwheat flour exhibited better antioxidative properties than the ethanolic extracts of wheat flour (Sedej et al., 2011b). The special advantage of incorporating buckwheat flour into bakery products is its ability to maintain antioxidant capacity after thermal treatments (Sakač et al., 2011).

Therefore, a number of gluten-free bakery products containing buckwheat have been developed, such as gluten-free bread (Wronkowska et al., 2010; Torbica et al., 2010), biscuits (Schober et al., 2003), spaghetti (Verardo et al., 2011) and crackers (Sedej et al., 2011a). The gluten replacement in bakery products represents a major technological challenge due to its essential structure-building properties. Removal of gluten impairs dough structure to develop properly during kneading and baking. Therefore, its absence often results in a liquid batter rather than a dough, with a poor colour products and other quality defects after baking (Galagher et al., 2004). In order to provide structure and retain gas, substances which have the ability to imitate viscoelastic properties of gluten are commonly used. Gums and hydrocolloids are one of the most important ingredients in gluten-free formulation for improving the texture and appearance of the final products (Mariotti et al., 2009).

Unlike bread and pasta, gluten network in biscuits and cookies has to be only slightly developed (Schober et al., 2003), which allows greater diversification among nutritionally improved ingredients which could be used in gluten-free cookie manufacturing. Therefore, gluten-free

1 cookies have the potential to be significant contributors of essential nutrients in the diet of celiac patients.

2  
3 Cookies are baked products which are most commonly consisted of three major components, i.e. flour, sugar and fat and low final amount of water. These ingredients are mixed together with other minor components to form dough (Zucco et al., 2011). Dough making and handling, cookie baking and quality of the final product are thus largely influenced by cookie dough components (Pareyt & Delcour, 2008). Cookie spread, i.e. the extent to which the dough piece spreads during baking represents one of the major quality parameter (HadiNezhad & Butler, 2009). Generally cookie spread is associated to sugar, fat and protein content. Due to high fat and sugar content in cookie recipes, gluten network development is limited. However, proteins in wheat flour cookies are not functionally inert in cookie dough which is observed especially during the baking (Gaines, 1990). According to Pareyt et al. (2008) higher protein content results in decreased cookie spread. Cookie spread is also controlled by dough viscosity (HadiNezhad & Butler, 2009). Due to lower water content, cookie dough is generally more elastic and less extensible in comparison to bread dough. Since cookie dough rheology characterisation is related to dough handling properties and the dough tendency to contract, it is very important parameter in cookie quality evaluation (Pedersen et al., 2004).

18 Despite its importance, there is a lack in published research on rheological behaviour of gluten-free cookie dough. To the best of the Authors' knowledge, the only published papers concerning cookie or gluten-free dough rheology are those regarding wheat containing cookie dough (Pedersen et al., 2004) or gluten-free bread dough (Gural et al., 2003; Lazaridou et al., 2007).

22 The aim of this paper was to investigate the effect of substituting rice flour with buckwheat flour on the machineability of gluten-free cookie dough. Therefore, a step toward production of nutritionally improved gluten-free cookies which could be prepared in automated industrial processing systems was made. In order to achieve better sheetability, carboxymethylcellulose was also incorporated in formulation, since addition of hydrocolloids as gluten mimetics was already proven (Gallagher et al., 2004). The influence of buckwheat flour and carboxymethylcellulose on the production of gluten-free cookie dough of acceptable handling properties was evaluated by comparing their rheological behaviour to wheat-containing cookie dough properties. In order to study the structural aspects responsible for specific behaviour of rice flour/buckwheat flour/carboxymethylcellulose blends scanning electron microscopy was used for the integration

## 9 4 **2. Materials and methods**

### 10 5 11 6 **2.1. Materials**

12  
13  
14 7  
15  
16 8 Rice flour, RF (moisture 10.6%, protein 7.7% db, starch 88.8% db, lipids 0.44% db and sugars  
17 9 0.27% db), husked buckwheat flour, BF (moisture 11.3%, protein 12.3% db, starch 80.5% db,  
18 10 lipids 2.87% db and sugars 0.27% db) and wheat flour, WF (moisture 12.2%, protein 11.6% db,  
19 11 starch 84.1% db, lipids 1.31% db and sugars 1.44% db) were procured from Hemija Komerc,  
20 12 (Novi Sad, Serbia). Sodium carboxymethylcellulose, CMC was obtained from Alfa Aesar  
21 13 (Karlsruhe, Germany). Sodium bicarbonate, NaHCO<sub>3</sub> was purchased from Carl Roth (Karlsruhe,  
22 14 Germany) and DATEM - diacetyl tartaric acid esters of mono- and diglycerides of fatty acids  
23 15 (PANTEX DW 90) was purchased from Incopa (Illertissen, Germany). Vegetable fat-shortening  
24 16 (refined palm and sunflower oil) was obtained from Puratos (Groot-Bijgaarden, Belgium) while  
25 17 salt, granulated sugar and honey were purchased from local market.

### 37 19 **2.2. Cookie-making procedure**

38  
39 20  
40 21 In order to **determine gluten-free** cookie dough formulation, the ratio of principal ingredients was  
41 22 varied until the dough of good handling properties was made. The obtained recipe is presented in  
42 23 Table 1.  
43  
44

45  
46 24 **To examine the influence of buckwheat flour, rice flour was blended with 10, 20 and 30% of**  
47 25 **buckwheat flour. Cookie doughs of 100% rice flour and 100% wheat flour were prepared as**  
48 26 **control samples. Wheat containing cookies were produced without CMC. In order to get insight**  
49 27 **into the influence of carboxymethylcellulose, gluten-free formulation containing 20% of**  
50 28 **buckwheat flour without the addition of CMC was also prepared.**

51  
52 29 Cookie dough was made in a Farinograph mixing bowl (Brabender, Duisburg, Germany), at 30  
53 30 °C. Flour, salt, sugar, sodium bicarbonate, DATEM and CMC were sifted together and mixed for  
54 31 3 minutes. Subsequently, vegetable fat was added and mixed for additional 2 minutes. Finally,  
55  
56  
57

62  
63  
64  
65

1 water containing honey was added to the resulting mass, and mixed for 25 min. The obtained  
2 cookie dough was rested for 24 h at 8 °C in order to achieve the hydration of added CMC.  
3 Afterwards, the dough was tempered to room temperature and sheeted to a thickness of 4 mm  
4 with the help of a pilot scale dough sheeter (Mignon, Italy). Cookies were shaped using a cutter  
5 (60 x 55 mm) and baked at 170 °C for 12 min in a laboratory oven (MIWE gusto® CS,  
6 Germany). The baked cookies were cooled for 2 h and stored in polypropylene bags for further  
7 analysis.

### 2.3. Rheological testing of cookie dough

11 Rheological behaviour of cookie dough was determined immediately after the sheeting process,  
12 using a HAAKE Mars rheometer (Thermo Scientific, Karlsruhe, Germany). The rheometer was  
13 equipped with a 35 mm parallel plate measuring geometry. The plates were serrated in order to  
14 prevent the dough slippage. A dough sample was placed on the lower plate, and the upper plate  
15 was lowered until the gap of 1.0 mm was reached. The excess dough was trimmed and the edges  
16 were sealed with a paraffin oil to prevent the dough from drying during measurements. The  
17 sample was left to rest for 10 min before measurements, so that residual stresses could relax. All  
18 experiments were performed at 30 °C in triplicates.

19 Frequency sweeps test was carried out from 0.1 to 50 Hz, under a 5 Pa strain level, which was  
20 within a linear viscoelastic region of all cookie dough samples. The data of frequency sweeps  
21 were plotted as  $G'(f)$  and  $G''(f)$  in double logarithmic diagram and experimental data of  $G'$  vs.  $f$   
22 were fitted using the following equation:

$$G'(f) = K'f^{n'}$$

26 where  $G'$  is storage (elastic) modulus,  $K'$  is coefficient which represent the storage modulus at 1  
27 Hz (Peressini et al., 2000) and  $n'$  is coefficient which represents the slope of the curve in a log-  
28 log plot of  $G'$  versus the frequency (Sivaramakrishnan et al., 2004). The values of  $\tan \delta$ , which  
29 represents the ratio of energy lost or dissipated ( $G''$ ) to energy stored in the material and  
30 recovered from it per cycle of sinusoidal deformation ( $G'$ ) were also reported.

1  
2  
3  
4 1 Since frequency sweep test is a small deformation test which does not destroy the dough  
5  
6 2 structure, **creep-recovery test was** conducted immediately after frequency sweep measurements  
7  
8 3 on the same dough sample. Creep was measured at a shear stress of 50 Pa for 300 s, followed by  
9  
10 4 a recovery phase of 900 s at a stress of 0 Pa. Namely, initial experiments confirmed that the  
11  
12 5 tested cookie dough reached a steady viscous flow in this time range.

13 6 Creep data were described by Burgers model parameters, which can be expressed using the  
14  
15 7 following equation:

16  
17 8  
18  
19 9 
$$J(t) = J_0(t) + J_r(t) + J_n(t)$$

20 10  
21  
22  
23 11 or

24  
25 12  
26  
27 13 
$$J(t) = J_0 + J_m(1 - \exp(-t/\lambda)) + t/\eta_0$$

28  
29 14  
30  
31 15 where  $J_0$  is the instantaneous compliance,  $J_m$  is the viscoelastic compliance,  $\lambda$  is the mean  
32  
33 16 retardation time and  $\eta_0$  is the zero shear viscosity. Maximum creep compliance,  $J_{max}$ , elastic  
34  
35 17 compliance,  $J_e$  and viscous compliance,  $J_v$  were extracted from recovery curve. The parameters  
36  
37 18 are also presented in Figure 1.

38  
39 19  
40 20 **2.4. Scanning electron microscopy (SEM)**

41  
42 21  
43  
44 22 In order to prepare cookie dough samples for scanning electron microscopy imaging, the  
45  
46 23 procedure described by Ribotta et al. (2004) was followed. The samples were dried using CPD  
47  
48 24 030 BAL-TEC Critical Point Dryer (BAL-TEC AG, Liechtenstein) following coating with gold  
49  
50 25 (180 s / 30 mA / 50 mm distance) in a SCD 005 BAL-TEC Ionic Sputter Coater (BAL-TEC AG,  
51  
52 26 Liechtenstein). The images were obtained using the Jeol JSM 6460LV Scanning Electron  
53  
54 27 Microscope (Tokyo, Japan) with a 25 kV acceleration voltage. The micrographs were **taken**  
55  
56 28 **using the** magnification of 1000×.

57 29  
58  
59 30 **2.5. Textural properties of cookies**

1  
2  
3  
4 1  
5  
6 2 Cookie break strength was measured by a TA.XTPlus Texture analyzer (Stable Micro Systems,  
7  
8 3 UK) using a 3-Point Bending Rig (HDP/3PB) and 5 kg load cell in compression mode at a test  
9  
10 4 speed of 3 mm/s and the gap distance of the base plate of 55 mm. Textural analyses were  
11  
12 5 conducted after 24 h, at 20 °C, in nine replicates per batch.  
13  
14 6

## 15 7 **2.6. Dimensional properties of cookies**

16  
17 8  
18  
19 9 Dimensional characteristics of cookies were described as % contraction in the direction of  
20  
21 10 sheeting, % spread perpendicular to the direction of sheeting which represent changes in  
22  
23 11 dimensions after cutting and baking; and width and length eccentricity which represent  
24  
25 12 deformation from rectangular shape of the final product.

26 13 Cookies were evaluated for the contraction of the dough (% contraction) in the direction of  
27  
28 14 sheeting, the spread (% spread) perpendicular to the direction of sheeting and the width and  
29  
30 15 length eccentricity which were calculated as:  
31  
32 16

$$33 \quad \% \text{ contraction} = \frac{W_m - W}{W_m} \cdot 100 \quad \text{and} \quad \% \text{ spread} = \frac{L - L_m}{L_m} \cdot 100$$

$$34 \quad \text{width eccentricity} = \frac{\text{width of the cookie centre}}{\text{width of the cookie edges}}$$

$$35 \quad \text{length eccentricity} = \frac{\text{length of the cookie centre}}{\text{length of the cookie edges}}$$

36 17  
37 18  
38  
39  
40  
41 19  
42 20  
43 21  
44  
45 22  
46 23 where  $W$  and  $L$  are the width and length of six randomly selected cookies  $W_m$  (55 mm) and  $L_m$   
47  
48 24 (60 mm) are the width and length of the mold used.  
49  
50 25

## 51 26 **2.7. Sensory evaluation of cookies**

1  
2  
3  
4 1 The sensory evaluation of cookies was performed 24 h after baking by a panel of 20 consumers,  
5  
6 2 both male and female. A 5-point hedonic rating scale was used to evaluate the overall  
7  
8 3 acceptability of the cookie sample, with "1" being "dislike very much", "2" being "dislike  
9  
10 4 moderately", "3" being "neither like nor dislike", "4" being "like moderately " and "5" being  
11  
12 5 "like very much" (Moskowitz et al., 2004). Three coded samples per cookie formulation were  
13  
14 6 tested. Cookies were considered acceptable if their mean scores for overall acceptability were  
15  
16 7 above 3.  
17  
18 8

## 19 9 **2.8. Statistical analysis**

20  
21 10  
22  
23 11 Data were analyzed by one-way analysis of variance with Tukey's test, which was performed  
24  
25 12 using Statistica 8.0 (Statsoft, Tulsa, USA). The significance of differences among the mean  
26  
27 13 values was indicated at the 95% confidence level.  
28  
29 14

## 30 15 **3. Results and discussion**

### 31 32 16 33 17 **3.1. Properties of gluten-free doughs**

34  
35 18  
36  
37 19 According to mechanical spectra of analysed cookie doughs (Figure 2), storage modulus,  $G'$  was  
38  
39 20 higher than loss modulus,  $G''$  ( $\tan \delta < 1$ ) in the examined frequency range, indicating solid  
40  
41 21 elastic-like behaviour of gluten-free cookie doughs.

42  
43 22 The prevalence of elastic properties over viscous has been reported for gluten-free bread dough  
44  
45 23 containing rice flour (Lazaridou et al., 2007; Sivaramakrishnan et al., 2004; Torbica et al., 2010),  
46  
47 24 as well as for buckwheat flour dough (Han et al., 2011). However, since cookie dough is  
48  
49 25 characterized by low moisture and high fat and sugar content compared to bread dough, it  
50  
51 26 exhibited higher elastic modulus than gluten-free bread dough composed of rice and buckwheat  
52  
53 27 flour (Torbica et al., 2010). According to previously conducted studies, addition of fat (Gujral et  
54  
55 28 al., 2003) and reduction in water level in both gluten-free (Lazaridou et al., 2007) and wheat  
56  
57 29 (Phan-Thien & Safari-Ardi, 1998; Edwards et al., 1999) dough led to increase in dough elastic  
58  
59 30 modulus. Frequency sweep test has also showed a frequency dependence of both  $G'$  and  $G''$   
60  
61 31 modulus. In order to express the magnitude of the dependence of storage modulus on oscillation

1 frequency, the curves were fitted to power-law equation and the obtained coefficients are  
2 presented in Table 2. **Mean values of  $\tan \delta$  ( $G''/G'$ ) from 1 to 10 Hz are also shown in Table 2.**  
3 According to the results summarized in Table 2, rice cookie dough had higher values of  $K'$   
4 (storage modulus at 1 Hz) and lower values of  $\tan \delta$  in comparison to other tested samples  
5 expressing the properties of rigid and stiff material (Weipert, 1990). Moreover, the value of  $n'$   
6 was lower for rice dough than for wheat cookie dough indicating its frequency independent  
7 structural stability (Mohammed et al., 2011). Investigating the feasibility of rice dough for  
8 making rice bread, Sivaramakrishnan et al. (2004) have also revealed that rice dough exhibited  
9 higher dynamic moduli and lower frequency dependence than wheat flour. Addition of  
10 buckwheat flour in dough system decreased elastic modulus and increased  $\tan \delta$ , suggesting that  
11 presence of buckwheat flour lowered the strength **and elasticity** of gluten-free cookie dough. On  
12 contrary, addition of CMC resulted in a significant rise of storage modulus.  
13 The creep curve analysis for both creep phase and the recovery phase are also given in Table 2.  
14 In general, under the applied stress of 50 Pa which **did not** exceed the linear viscoelastic range,  
15 rice cookie dough exhibited the greater resistance to deformation as shown by the reduction of  
16 maximum creep compliance. Partial replacement of rice flour with buckwheat flour led to rise in  
17 maximum creep compliance values, thus increasing dough extensibility. A significant increase in  
18 viscoelastic compliance and slight increase in instantaneous compliance were also noticed with  
19 the increase in buckwheat addition level, while the zero shear viscosity was lower. According to  
20 Edwards et al. (2001) zero or steady-state viscosity **decreases** with reduction in dough strength  
21 measured by Extensograph. Creep results were in accordance with oscillation results which also  
22 revealed the decrease in dough strength with increase in buckwheat flour content. Higher  
23 thermo-mechanical weakening of buckwheat flour dough in comparison to rice dough during  
24 dough kneading was reported earlier (Torbica et al., 2008; Dapčević Hadnađev et al., 2011).  
25 Results concerning the dough elastic properties ( $\tan \delta$  in frequency sweep test and relative elastic  
26 compliance in creep-recovery test) were also in accordance. **During the recovery phase,**  
27 **recovered deformation which was** presented as relative elastic compliance, was higher for pure  
28 rice dough than for buckwheat supplemented doughs. However, this difference in dough elastic  
29 character was only significant at 30% buckwheat replacement level. Moreover, among the tested  
30 samples, cookie dough containing 30% of buckwheat flour expressed the highest viscous  
31 properties, as revealed by relative viscous compliance value.

1  
2  
3  
4 1 In order to determine the structural organization in cookie dough samples responsible for  
5 differences in dough strength and elasticity, SEM imaging was performed (Figure 3).  
6  
7  
8 2 Namely, Edwards et al. (2001) have revealed that strength of durum wheat dough, expressed as  
9  
10 3 high steady-state viscosity and low extensibility, primarily depends on density of physical  
11 4 crosslinks present. Since in gluten-free dough gluten complex can not be formed, the differences  
12 5 in dough strength may be ascribed to differences in size and shape of their native starch granules  
13 6 (Singh et al., 2003).  
14  
15  
16 7  
17 8 Micro-structural observation of composite dough (containing 10 and 30% of buckwheat flour)  
18 9 revealed that buckwheat starch granules disturbed the structure of rice dough starch granule  
19 10 network which can influence the dough weakening determined during rheological tests. Gluten-  
20 11 free dough structures (Figure 3 a, b) were characterized by the regions of densely packed rice  
21 12 starch granules (2–9  $\mu\text{m}$ ) which were partially covered with proteins and CMC. This continuous  
22 13 phase was disrupted with the regions of irregular in shape small starch granules ( $< 7 \mu\text{m}$ )  
23 14 grouped in the clusters which is a characteristic of buckwheat flour (Mariotti et al., 2008;  
24 15 Hatcher et al., 2008). Furthermore, it can be observed that the clusters with the CMC network  
25 16 fragments and rice proteins fragments on the surfaces are more noticeable for gluten free-dough  
26 17 with 30% of buckwheat flour. In order to compare gluten-free doughs with gluten-containing  
27 18 dough, wheat cookie dough micrographs (Figure 3 c) were also taken. Wheat dough was  
28 19 characterized by the presence of small ( $< 10 \mu\text{m}$ ) and large starch granules ( $>15 \mu\text{m}$ ) which are  
29 20 densely distributed in partially formed protein matrix. These findings were in accordance with  
30 21 Kim et al. (2003) and Naruenartwongsakul et al. (2008). However, according to obtained  
31 22 micrographs starch granules in gluten-free doughs as well as in wheat flour dough were not  
32 23 completely covered with protein and CMC matrix due to less water content in cookie  
33 24 formulation in comparison to common bread formulation where the higher hydration led to  
34 25 continuous protein network formation. This was in agreement with Létang et al. (1999) who  
35 26 reported that in bread dough, starch granules were covered with a continuous protein film and  
36 27 were less visible than in less hydrated doughs such as cookie dough.  
37 28 Addition of CMC led to increase in dough firmness as revealed by decrease in maximum creep  
38 29 compliance and increase in zero shear viscosity and  $G'$ . The similar results were obtained for  
39 30 gluten-free bread dough (Lazaridou et al., 2007). Possible reasons for the increase in cookie  
40 31 dough firmness might be that (1) addition of CMC improved the starch granules cohesiveness,

1  
2  
3  
4 1 and (2) due to increase in water absorption level in CMC containing sample dough consistency  
5  
6 2 increase.

7  
8 3 In general, the gluten-free dough containing CMC and buckwheat flour between 20 and 30%  
9  
10 4 showed similar storage modulus, instantaneous and maximum creep compliance, zero shear  
11  
12 5 viscosity and recovered deformation values to that of wheat cookie dough. Therefore, it could be  
13  
14 6 concluded that addition of buckwheat flour and CMC in rice dough resulted in gluten-free cookie  
15  
16 7 dough of acceptable handling properties. Namely, inclusion of buckwheat flour into gluten-free  
17  
18 8 cookie dough led to soft, viscous, deformable dough, easy to handle in comparison to rice dough,  
19  
20 9 but due to presence of CMC, it was strong enough to resist sheeting without sticking to rollers  
21  
22 10 and maintain acceptable shape.

### 23 11 24 12 **3.2. Properties of gluten-free cookies**

25  
26 13  
27  
28 14 In order to determine the quality of gluten-free cookies, physical (texture, contraction and spread,  
29  
30 15 eccentricity) and sensory (top surface cracking and overall acceptability) attributes of final  
31  
32 16 products were evaluated.

33  
34 17 Unlike the rheological experiments, quality of gluten-free cookies that did not contain CMC  
35  
36 18 could not be evaluated. The absence of CMC resulted in cookie dough which was insufficiently  
37  
38 19 cohesive for handling and shaping. Therefore, the dough without CMC addition, which was  
39  
40 20 shaped with a rolling pin, resulted in cookies of irregular shape and more cracked surface than  
41  
42 21 cookies containing CMC (Figure 4). Moreover, wheat containing cookies were also excluded  
43  
44 22 from further evaluation although their dough was characterized with good machineability.  
45  
46 23 Namely, in order to optimize the gluten-free formulations which will result in cookies of  
47  
48 24 acceptable quality, amount of added water and fat were higher in comparison to standardized  
49  
50 25 wheat dough cookie formulation, which made the comparison to wheat control cookie irrelevant.  
51  
52 26 In addition, the consciously comparison of gluten-free to wheat cookies was avoided during  
53  
54 27 hedonic test.

55  
56 28 In general, the characteristics of a high quality cookie are the adequate hardness (enough to  
57  
58 29 maintain its shape during transportation but able to fracture easily when chewed in the mouth), a  
59  
60 30 high spread ratio (diameter/thickness), low eccentricity, brownish colour, attractive appearance  
61  
62 31 (no surface cracks) and pleasant flavour.

1 The effect of buckwheat incorporation onto textural properties of gluten-free cookies is  
2 summarized in Table 3, whereas dimensional changes of cookies are presented in Figure 5.  
3 Textural properties of cookies were expressed as **hardness/firmness and fracturability/brittleness.**  
4 **Maximum peak force recorded from force/distance curve (the maximum force required to break**  
5 **a cookie or maximum resistance of cookie when break)** has been reported as hardness, firmness  
6 or breaking strength (Bourne, 2002; Mamat et al., 2010; Pareyt et al., 2009). **Fracturability**  
7 **(Bourne, 2002) or brittleness (Wekwete & Navder, 2008) has been determined as** peak distance  
8 which represents the distance travelled by the blade through the cookie in mm before the cookie  
9 will break or the distance the cookie will deform before breaking. According to the results  
10 presented in Table 3, partial replacement of rice with buckwheat flour led to decrease in cookie  
11 hardness and fracturability. However, no significant difference in cookie hardness and brittleness  
12 was observed with the increase in buckwheat flour replacement level. The experiments  
13 performed by Mamat et al. (2010), Pareyt et al. (2009) and Lee et al. (2005) revealed that wheat  
14 cookies containing optimal amount of fat and sugar have the hardness and brittleness values in  
15 the range 20 to 30 N and 0.65 to 0.9 mm, respectively, which is in agreement with the values  
16 obtained for buckwheat containing cookies. Therefore, it could be expected that cookies enriched  
17 with buckwheat flour would be more acceptable by consumers in terms of texture since high  
18 fracturability of rice cookies could have negative impact on cookie chewiness.  
19 Dimensional characteristics of biscuits (Figure 5) were described as % contraction in the  
20 direction of sheeting, % spread perpendicular to the direction of sheeting which represent  
21 changes in dimensions after cutting and baking; and width and length eccentricity which  
22 represent deformation from rectangular shape of the final product. Similar dimensional  
23 properties were used by Pedersen (2004) in order to evaluate the baking characteristics of  
24 different wheat cultivars, with slight modification due to difference in cookie shape. As it can be  
25 seen from Figure 5, dimensions of cookies were strongly affected ( $p < 0.05$ ) by buckwheat flour  
26 addition. Increase in buckwheat flour substitution level led to decrease in % contraction and  
27 increase in % spread and eccentricity.  
28 The results obtained from textural and dimensional measurements of cookies were in accordance  
29 with the rheological properties of cookie dough. **Rice** dough which was stronger (higher elastic  
30 modulus, lower maximum creep compliance) and more elastic (lower  $\tan \delta$ , higher recovery)  
31 yielded harder cookies which were more shrunk and less deformed from regular shape than

buckwheat containing cookies. Schober et al. (2003) have also revealed that rheological properties of cookie dough determine the quality of final product. Accordingly, a firm, non-sticky dough results in firm and thin round biscuits whereas soft, sticky dough yields soft and thick oval biscuits. Wani et al. (2010) have also reported that less extensible cookie doughs resulted in harder cookies. On the other hand, Maache-Rezzoug et al., (1998) have found that shrinkage after cutting increases with dough elasticity, which results in decreased biscuit length. Therefore, the addition of buckwheat flour, which influenced a decrease in dough elasticity, led to increase in cookie spread. Increased cookie spread of buckwheat enriched cookies can be also ascribed to the differences in rice and buckwheat starch gelatinization. As it was already shown, the addition of buckwheat to rice flour lowers the maximum peak torque during gelatinization (Torbica et al., 2010), which lead to decrease in dough viscosity and increase in cookie spread (Tsen et al, 1975).

In order to determine the overall acceptability of gluten-free cookies, the sensory evaluation was performed. The sensory characteristics of the cookies were screened by untrained panellists using a five point hedonic scale (Figure 6). Although the results obtained by untrained panellists are usually less precise and replicable (Barylko-Pikielna & Matuszewska, 1996) than those obtained by trained panellists, the judgment of untrained panellists, as future consumers, is certainly very valuable (Arifin et al., 2010) before launching a new food product into the market. According to untrained panellist evaluation, all gluten-free cookie formulations were acceptable, since they received scores much higher than 3 ranging from 3.5 to 4.2. Even though rice cookies were visually superior to those containing buckwheat flour in terms of eccentricity (Figure 4), buckwheat enriched cookies were rated higher for overall acceptability. Sensory characteristics influencing higher scores for overall acceptability were pleasant smell and taste of cookies prepared from buckwheat flour. Moskowitz & Krieger (1995) have shown that taste/flavour sensory attribute is more important than appearance. By ranking the importance for attribute liking Moskowitz & Krieger (1995) have obtained the following order: taste/flavour > texture > appearance.

It has been previously shown that incorporation of buckwheat flour in either gluten-free bread (Torbica et al., 2010) or wheat containing bread (Lin et al., 2009) and pasta (Jambrec et al., 2011) can increase the flavour and mouth feel sensory attributes of the product compared to controls containing only rice or wheat flour. However, during investigation of the influence of

1 buckwheat flour on sensory properties of Turkish noodles, Bilgiçli (2009) revealed that taste  
2 scores increased up to the 20% buckwheat flour level while the further increase in buckwheat  
3 flour content led to a decrease in taste scores. The results presented in this study have also shown  
4 that increase in buckwheat flour content from 20 to 30% did not significantly influence ( $p >$   
5 0.05) the overall acceptability of gluten-free cookies.

#### 6 7 **4. Conclusions**

8  
9 **Production of gluten-free cookies of acceptable processing properties and preferred sensory and**  
10 **textural characteristics was performed.** The aim of the present study was to investigate the  
11 influence of buckwheat flour and CMC addition on rheological parameters and quality of gluten-  
12 free cookies.

13  
14 As revealed by **decrease in maximum creep compliance and increase in zero shear viscosity and**  
15  **$G'$ , the addition of CMC resulted in increased dough strength.** Namely, the absence of CMC led  
16 to cookie dough of insufficient cohesion for handling and shaping, which resulted in cookies of  
17 irregular shape and more cracked surface than cookies containing CMC. **Rice cookie dough**  
18 **expressed higher storage modulus at frequency 1 Hz, lower values of  $\tan \delta$  and the greater**  
19 **resistance to deformation than the wheat and buckwheat containing doughs.** The addition of  
20 **buckwheat flour led to rise in maximum, viscoelastic and instantaneous compliances and**  
21 **increase in  $\tan \delta$ , while the zero shear viscosity and storage modulus were lower.** Consequently,  
22 **the inclusion of buckwheat flour into gluten-free rice dough decreased dough elasticity and**  
23 **extensibility.** In general, the gluten-free dough containing CMC and buckwheat flour between 20  
24 and 30% substitution level resembled the wheat cookie dough in terms of dough strength and  
25 resistance to deformation. **Moreover it was found that creep results were in accordance with**  
26 **oscillation results which also revealed the decrease in dough strength with increase in buckwheat**  
27 **flour content.** The addition of buckwheat flour and CMC in rice dough resulted in soft, viscous,  
28 **deformable dough which was easy to handle and strong enough to resist sheeting and maintain**  
29 **acceptable shape.** Microstructural observation revealed that gluten-free dough structures were  
30 characterized by the regions of densely packed rice starch granule structure which was disrupted  
with the regions of irregular in shape small starch granules grouped in the clusters.

1 This study also showed that partial replacement of rice with buckwheat flour led to decrease in  
2 cookie hardness, fracturability and % contraction and increase in % spread and eccentricity.  
3 Moreover the results from textural and dimensional measurements of cookies were in accordance  
4 with the rheological characteristics of cookie dough. Buckwheat supplemented dough which was  
5 softer and more viscous (lower elastic modulus, higher maximum creep compliance, higher  $\tan$   
6  $\delta$ , lower recovery) yielded softer and more brittle cookies which were more deformed from  
7 regular shape than control rice cookies. According to the sensory evaluation, performed by  
8 untrained panellists, buckwheat enriched cookies were rated higher for overall acceptability.
